An initial outlook at the austral summer 2020-2021 sea-ice forecasts in the Southern Ocean

Coordinating Seasonal Predictions of Sea Ice in the Southern Ocean

The Sea Ice Prediction Network South

The Sea Ice Prediction Network South (SIPN South) is an international project endorsed by the Year of Polar Prediction (YOPP). Its goal is to make an initial assessment of the ability of current systems to predict Antarctic sea ice globally and regionally, with a focus on the summer season. The project has three strategic objectives:

1. Provide a focal point for seasonal outlooks of Antarctic sea ice (winter and summer), where the results are exchanged, compared, discussed and put in perspective with those from the Arctic thanks to interactions within the (Arctic) SIPN,
2. Provide news and information on the state of Antarctic sea ice, highlight recent published research, report ongoing observational campaigns and disseminate upcoming events (conferences, workshops, webinars, etcetera),
3. Coordinate realistic prediction exercises, focusing on summer, and aligned with the Year Of Polar Prediction (YOPP)’s Special and Targeted Observing Periods (SOPs and TOPs). A TOP is scheduled for austral fall 2022.

We remind the reader that SIPN South is not an operational forecasting exercise. A brief assessment of forecast skill was performed in Massonnet et al. (2018, 2019, 2020) for the predictions of past years.

Forecasting sea ice during austral summer 2020-2021

We issued a call on November 15th, 2020, to collect forecasts covering the period December 1st 2020-February 28th 2021.

So far, we have received 13 submissions (258 forecasts) and would like to thank all contributors for their participation. We expect two to three additional submissions within the next days. New submissions will be displayed in future reports but, in any case, they will not use data past December 1st 2020.

We asked contributors to provide, in order of descending priority, (1) the total Antarctic sea-ice area (“SIA”) for each day of December-February 2020-2021, (2) the sea-ice area per 10° longitude bands (“rSIA”) for each day of December-February 2020-2021, (3) the sea-ice concentration (“SIC”) for each day of December-February
2020-2021, and (4) the mean grid cell sea-ice thickness ("SIV") for each day of December-February 2020-2021.

**Table 1.** Information about contributors to the summer 2020-2021 coordinated sea ice forecast experiment.

*received as monthly data, interpolated daily
** received as Sea Ice Probability

**Circumpolar sea-ice area**

Fig. 1 shows the total sea-ice area (SIA) forecasted for each day of December-January-February 2020-2021. We stress that SIA is not a very physical diagnostic, but it gives a first impression on how the forecasts behave. In this figure, we have also

![Figure 1](image-url)
plotted for reference the sea-ice area from two observational references, the NSIDC-0081 product (Maslanik and Stroeve, 1999) and the OSI-401-b product (Tonboe et al., 2017). The behavior of the CNRM curve is due to post-processing applied to the raw forecast (V. Guemas, personal communication).

**Spatial information**

![Figure 2](image)

**Figure 2.** Ensemble mean of February 2021 monthly mean sea ice concentration, as forecasted by the seven groups that submitted daily sea ice concentration information. The very thin salmon lines are the ice edge position for each forecast member, determined as the 15% contour line of the monthly mean sea ice concentration for the member.
Seven groups submitted the spatial information of daily sea-ice concentration for each day of December-February 2020-2021. Groups provided several members (from 1 to 51) in order to sample uncertainty associated to the (unpredictable) evolution of the climate system, so that each member of a given model could be seen as a possible realization of that model. Fig. 2 displays the ensemble mean of monthly mean sea-ice concentration for February 2020, together with the sea-ice edge lines (15% sea-ice concentration contours) for each member. Sea-ice presence is forecasted in the Weddell Sea along the Antarctic Peninsula in all contributions. This is a region where the ice is climatologically present. There is high inter-model uncertainty regarding the presence of ice in the Ross Sea in February 2021, as for previous years.
The maps of ensemble February mean sea-ice concentration (Fig. 2) are useful to appreciate the expected average conditions that could prevail in February, but are difficult to interpret for potential final users of the forecasts. Therefore, we also show the daily probability of sea-ice presence (Fig. 3). Green pixels are those where the ice is extremely unlikely to be present, while red ones are those where the ice is extremely likely to be present.

**Figure 3.** Probability of ice presence for the 15th of February 2021, as forecasted by the groups that submitted daily sea ice concentration information. The probability of presence corresponds to the fraction of ensemble members that simulate sea ice concentration larger than 15% in a given grid cell, for that day. For AWI-SDAP, probability of sea ice presence was given directly.
Next steps

After February 2021, we will evaluate the forecasts with two observational references. A more detailed analysis of this first exercise will be published in Spring 2021.
